Assume we have a curve described by parametric functions  $x = f(t)$  and

 $y = g(t)$  defined on some interval  $a \le t \le b$ .

As an approximation we can break the curve up as follows:

Where the points are  $A = (x_0, y_0), (x_1, y_1) \dots (x_n, y_n) = B$ We know that between any two points the length is  $L \approx \sum_{i} \sqrt{(\Delta x_i)^2 + (\Delta y_i)^2}$  $\boldsymbol{0}$ *n*  $i$  *j*  $\left(\frac{\Delta y_i}{\Delta x_i}\right)$ *i*  $L \approx \sum \sqrt{(\Delta x_i)^2 + (\Delta y_i)^2}$  $\approx \sum_{i=0} \sqrt{(\Delta x_i)^2 + (\Delta y_i)^2}$  where  $\Delta x = x_{i+1} - x_i$  and  $\Delta y = y_{i+1} - y_i$ Note however that  $f'(t) \approx \frac{\Delta x_i}{\Delta t}$ *t*  $\approx \frac{\Delta}{2}$  $\frac{\Delta x_i}{\Delta t}$  and  $g'(t) \approx \frac{\Delta y_i}{\Delta t}$ *t*  $\approx \frac{\Delta}{\cdot}$ ∆ So we can express  $\Delta x_i = f'(t) \Delta t$  and  $\Delta y_i = g'(t) \Delta t$ 

Rewriting our sum  $L \approx \sum_{i=1}^{n} \sqrt{(f'(t_i)\Delta t_i)^2 + (g'(t_i)\Delta t_i)^2}$ 0  $\int (t_{_t}) \Delta t_{_i}^{\,2} + (g^{\,\prime})^2$ *n*  $\iota_i$  *j*  $\Delta \iota_i$  *j*  $\iota_j$   $\Delta \iota_i$ *i*  $L \approx \sum_i \sqrt{(f'(t_i)\Delta t_i)}^2 + (g'(t_i)\Delta t_i)^2$  $\approx \sum_{i=0} \sqrt{(f'(t_i)\Delta t_i)}^2 + (g'(t_i)\Delta$ Letting the  $\Delta t$ 's go to zero we get the integral

$$
L = \int_{a}^{b} \sqrt{(f'(t))^{2} + (g'(t))^{2}} dt
$$
 or  

$$
L = \int_{a}^{b} \sqrt{\left(\frac{df}{dt}\right)^{2} + \left(\frac{dg}{dt}\right)^{2}} dt
$$

## Example 1:

Let  $x = t^2$  and  $y = t^2$  be parametric equations for a curve. What is the length of this curve from  $(1,1)$  to  $(4,8)$ 

For  $x = 1$ ,  $t = 1$  and for  $x = 4$ ,  $t = 2$  so we have the integral:

$$
L = \int_{1}^{2} \sqrt{\left(\frac{df}{dt}\right)^{2} + \left(\frac{dg}{dt}\right)^{2}} dt = \int_{1}^{2} \sqrt{\left(2t\right)^{2} + \left(3t^{2}\right)^{2}} dt = \int_{1}^{2} \sqrt{4t^{2} + 9t^{4}} dt = \int_{1}^{2} t \sqrt{4 + 9t^{2}} dt = \frac{1}{18} \int_{1}^{2} 18t \sqrt{4 + 9t^{2}} dt =
$$

Subtituting  $u = 4 + 9t^2$  we find that  $du = 18t$  so

$$
L = \frac{1}{18} \int_{1}^{2} 18t \sqrt{4 + 9t^2} dt = \frac{1}{18} \int \sqrt{u} du = \frac{1}{18} \left[ \frac{2u^{3/2}}{3} \right] = \frac{1}{27} \left[ \left( 4 + 9t^2 \right)^{3/2} \right]_{1}^{2} = \frac{1}{27} \left[ \left( 40 \right)^{3/2} - \left( 13 \right)^{3/2} \right] = \frac{1}{27} \left[ 80 \sqrt{10} - 13 \sqrt{13} \right]
$$

Note that if we are given a function in terms of *x* we can treat *x* as a parameter giving the equations  $x = x$  and  $y = f(x)$ 

Since  $\frac{dx}{1} = 1$ *dx*  $= 1$  our formulae becomes

$$
L = \int_{a}^{b} \sqrt{\left(\frac{df}{dx}\right)^2 + 1} dt
$$

Example 2:

Find the length of the arch of the parabola  $y^2 = x$  from  $(0,0)$  to  $(1,1)$ 

Here we treat  $y$  as the parameter so we have

$$
L = \int_0^1 \sqrt{\left(\frac{dy^2}{dy}\right)^2 + 1} \, dy = \int_0^1 \sqrt{4y^2 + 1} \, dy =
$$

Substitute  $u = 2y$  so that 2  $\frac{du}{dt} = dy$  giving the integral  $\frac{1}{2} \int \sqrt{u^2 + 1}$  $\frac{1}{2}$  ∫  $\sqrt{u^2 + 1}$  *du* From our table #21 we have

$$
\int \sqrt{a^2 + u^2} \, du = \frac{u}{2} \sqrt{a^2 + u^2} + \frac{a^2}{2} \ln \left( u + \sqrt{a^2 + u^2} \right) + c
$$
\n
$$
\frac{1}{2} \int \sqrt{u^2 + 1} \, du = \frac{1}{2} \left[ y \sqrt{1 + 4y^2} + \frac{1}{2} \ln \left( 2y + \sqrt{4y^2 + 1} \right) \right] =
$$
\nThis gives us\n
$$
\frac{1}{2} \left[ \sqrt{5} + \frac{\ln \left( 2 + \sqrt{5} \right)}{2} - \left( 0 + \frac{1}{2} \ln \left( 1 \right) \right) \right] = \frac{\sqrt{5}}{2} + \frac{\ln \left( 2 + \sqrt{5} \right)}{4}
$$

Try Handout Problems

Average Value of a function.

Let's say you were to take the temperature every hour on the hour for 24 hours getting readings  $T_0, T_1, ..., T_2$ , then the average temperature for the day would be approximately

$$
Avg \approx \frac{\sum_{i=0}^{23} T_i}{24}
$$

If you were to then increase the readings to 48, 96, etc. You would end up with an integral for the average temperature that looks like this:

$$
Avg = \frac{1}{24} \int_{24 hours} T(t) dt
$$

We define a more general formula for the average of a function on an interval  $[a,b]$  as

$$
Avg = \frac{1}{b-a} \int_{a}^{b} f(x) \, dx
$$

Note and important feature of this. If the function is continuous, then there must some  $x = c$  such that  $f(c) = Avg$ .

Simplistic reason why:

Since the function is bounded there will be a maximum and minimum value of the function. It should be clear that  $\min \leq Avg \leq \max$ .

But because of the function is continuous, it must pass through every value of the function between the min and max. So there must be a value c for which  $f(c) = Avg$ .

This is called the mean value theorem..

Example: for  $f(x) = 1 + x^2$  on the interval  $[-1, 2]$  find the average value of the function and find a *c* such that  $f(c) = Avg$ 

First find 
$$
\frac{1}{2-1} \int_{-1}^{2} 1 + x^2 dx = 2
$$

Then find  $1 + c^2 = 2$ 

Note that in this case, *c* can be either 1 or -1
